

David Adeyemo

1. Allow the user to enter two exam scores from the keyboard. The first exam is worth 60% of the total points and the second exam is worth 40%. Calculate the total score by multiplying each exam score input by the respective weighting then add the two results together. Display the total.

Input	Process	Output
exm1		
exm2	$(\text{exm1} * .6) + (\text{exm2} * .4) =$ total score	Total score is''
Total_score		

2. Given the current stock price and quantity of stock, display the current value of the stock in your portfolio.

Input	Process	Output
crntstock	$\text{Crnstock} * \text{qstock} = \text{crn value}$	Stock total value:
qshare		
Crnvalue		

3. Enter the total for a meal. Compute a tip at 15%. Display total, tip and total with tip.

Input	Process	Output
mtotal		
tip	Tip total = mtotal * tip	Meal total:
Total with tip	Total with tip= total + mtotal	Tip:
		Total with tip:

4. The purchase price and current price of a stock is entered into your program.
Display the percentage increase or decrease of the stock.

Input	Process	Output
Purchase_price		
Current_price	Percentagechange= <i>(currentprice - purchase_price)/purchase price</i>	Stock increases a percent of:
Percentage_change		or
		Stock decreases by a percent of:
		Stock stays the same

5. You are setting up a business and need to compute the break even point. This indicates how many items you must sell at a given price to cover your overhead. Enter fixed costs, price per unit and cost per unit into your program. Compute the break even point by dividing fixed costs by the difference of price per unit and cost per unit.

Input	Process	Output
Break even point		
Fixed cost	Fixed cost / (price per unit - cost per unit)	You must sell _ to break even
Price per unit		

Cost per unit
